

AI-POWERED FERTILITY TREATMENT & FOLLOW-UP ASSISTANT

PROBLEM STATEMENT

In fertility care, patients often undergo multiple treatment cycles such as OI, IUI, IVF stimulation, OPU, embryo transfer, and pregnancy follow-up. These cycles generate large volumes of patient data across EMR records, including investigations, medications, stimulation charts, follicular development, oocyte and embryo details, treatment outcomes, adverse events, and doctor notes.

The challenge is to develop an AI-powered clinical assistant that can intelligently retrieve relevant information from a patient's historical fertility records and provide a concise, structured, and source-traceable treatment summary to help doctors quickly understand the patient's treatment journey and prepare for follow-up.

PARTICIPANTS SHOULD CONSIDER

- Patient's previous treatment cycles
- Investigation and laboratory reports
- Medication history
- Stimulation protocols and follicular development
- Oocyte retrieval and embryo details
- Previous treatment outcomes
- Pregnancy history
- Adverse events
- Current treatment stage
- Pending investigations and follow-ups
- Source/reference for every important retrieved fact

EXPECTED OUTCOME

A prototype where a doctor selects/searches for a patient and receives a structured flow such as: Patient → Treatment Timeline → Relevant Records → AI Summary → Follow-up Information → Source Records.

CLINICAL SAFETY

The solution should support the doctor's review, not replace clinical decision-making, and should minimize unsupported or hallucinated information.
