

TALENT DECISION INTELLIGENCE OS

PROBLEM STATEMENT

Talent information is often fragmented across ATS, VMS, MSP, HRIS, job boards, staffing suppliers, interview records, assessments, market-rate databases, internal employees and contractors. Despite having this data, organizations may still begin a requisition by immediately asking recruiters to find an external candidate in a specific location.

Develop a Talent Decision Intelligence OS that analyzes internal and external talent signals before recruiting begins. The system should challenge the initial requisition assumptions and help decision-makers compare whether a need is best addressed by building skills internally, buying external talent, borrowing contingent talent, automating work or changing location.

CORE REQUIREMENTS

- Integrate or simulate data from ATS, HRIS, VMS/MSP, contractors, job boards and talent-market sources.
- Normalize job titles and skills so comparable supply can be analyzed across multiple systems.
- Estimate talent supply, expected time-to-fill and compensation ranges for selected roles and locations.
- Identify internal employees with partial or strong skill matches and highlight potential development paths.
- Identify existing contractors who may satisfy the requirement or be candidates for conversion.
- Compare alternate locations and remote talent pools using consistent workforce criteria.
- Recommend sourcing channels or talent pools based on the requirement and available evidence.
- Present an explainable Build | Buy | Borrow | Automate | Relocate recommendation with supporting data.

EXPECTED WORKFLOW

A suggested flow is: Workforce Need → Role/Skill Analysis → Internal Talent → Contractor Talent → External Market → Location & Compensation Comparison → Build/Buy/Borrow/Automate/Relocate Options → Human Decision → Recruiting or Development Action.

EXPECTED OUTCOME

The prototype should transform a simple requisition into a workforce-intelligence brief containing supply indicators, internal matches, contractor options, compensation guidance, location alternatives and recommended next actions. The system should support decision-makers rather than automatically making workforce decisions on their behalf.
